# Imperfect Information Extensive Form Games

CMPUT 654: Modelling Human Strategic Behaviour

S&LB §5.2-5.2.2

# Assignment #1

- Assignment #1 is now available on eclass
  - Worth approximately 19% of your total mark
  - Don't leave it to the last minute
- Due Tuesday Feb 6 at 11:59pm
  - One week from today

# Assignment Hint: Mixed Strategy Nash by Hand

- Recall that if we know the support of an equilibrium in a two-player game we can compute its equilibrium with an LP
- For small games, you can just solve a system of equations for the probabilities of each action by hand.

## **Key points:**

- 1. If player i is mixing between two strategies in equilibrium, then they must both be best responses
- 2. Whether two strategies are best responses for i depends upon the probabilities that the **other player** plays their strategies

$$\sum_{\substack{a_{-i} \in \sigma_{-i} \\ a_{-i} \in \sigma_{-i}}} s_{-i}(a_{-i})u_{i}(a_{i}, a_{-i}) = v_{i} \qquad \forall i \in \{1, 2\}, a_{i} \in \sigma_{i}$$

$$\sum_{\substack{a_{-i} \in \sigma_{-i} \\ s_{i}(a_{i}) \geq 0}} s_{-i}(a_{-i})u_{i}(a_{i}, a_{-i}) \leq v_{i} \qquad \forall i \in \{1, 2\}, a_{i} \notin \sigma_{i}$$

$$\sum_{\substack{a_{i} \in \sigma_{-i} \\ s_{i}(a_{i}) = 0}} \forall i \in \{1, 2\}, a_{i} \notin \sigma_{i}$$

$$\forall i \in \{1, 2\}, a_{i} \notin \sigma_{i}$$

$$\forall i \in \{1, 2\}, a_{i} \notin \sigma_{i}$$

$$\forall i \in \{1, 2\}, a_{i} \notin \sigma_{i}$$

## Recap: Perfect Information Extensive Form Game

#### **Definition:**

A finite perfect-information game in extensive form is a tuple  $G = (N, A, H, Z, \chi, \rho, \sigma, u)$ , where

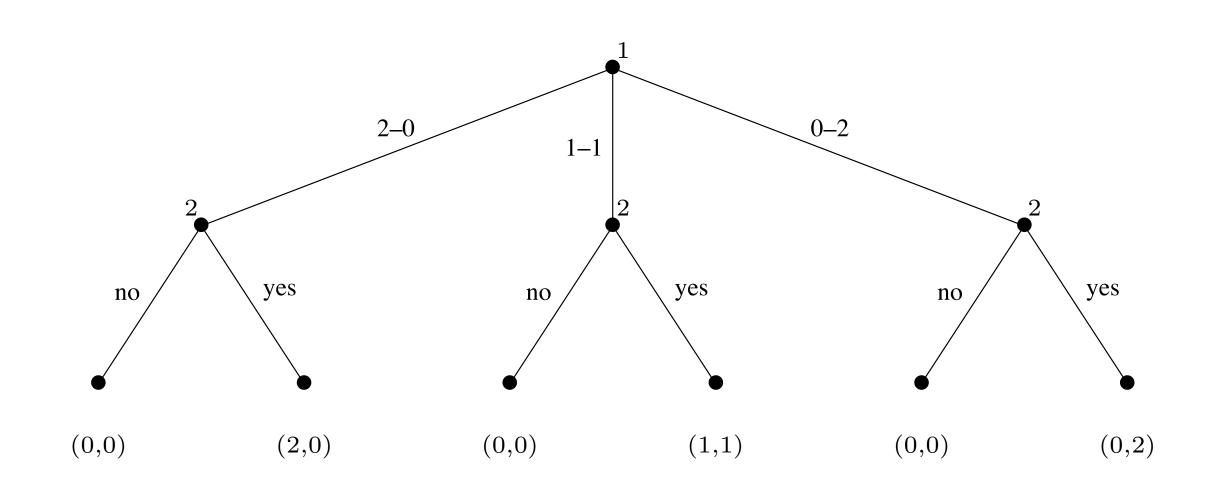

- N is a set of n players,
- A is a single set of actions,
- *H* is a set of nonterminal choice nodes,
- Z is a set of **terminal nodes** (disjoint from H),

 $\chi: H \to 2^A$  is the action function,

 $\rho: H \to N$  is the player function,

 $\sigma: H \times A \to H \cup Z$  is the successor function,

 $u=(u_1,u_2,...,u_n)$  is a profile of **utility functions** for each player, with  $u_i:Z\to\mathbb{R}$ .

# Recap: Pure Strategies

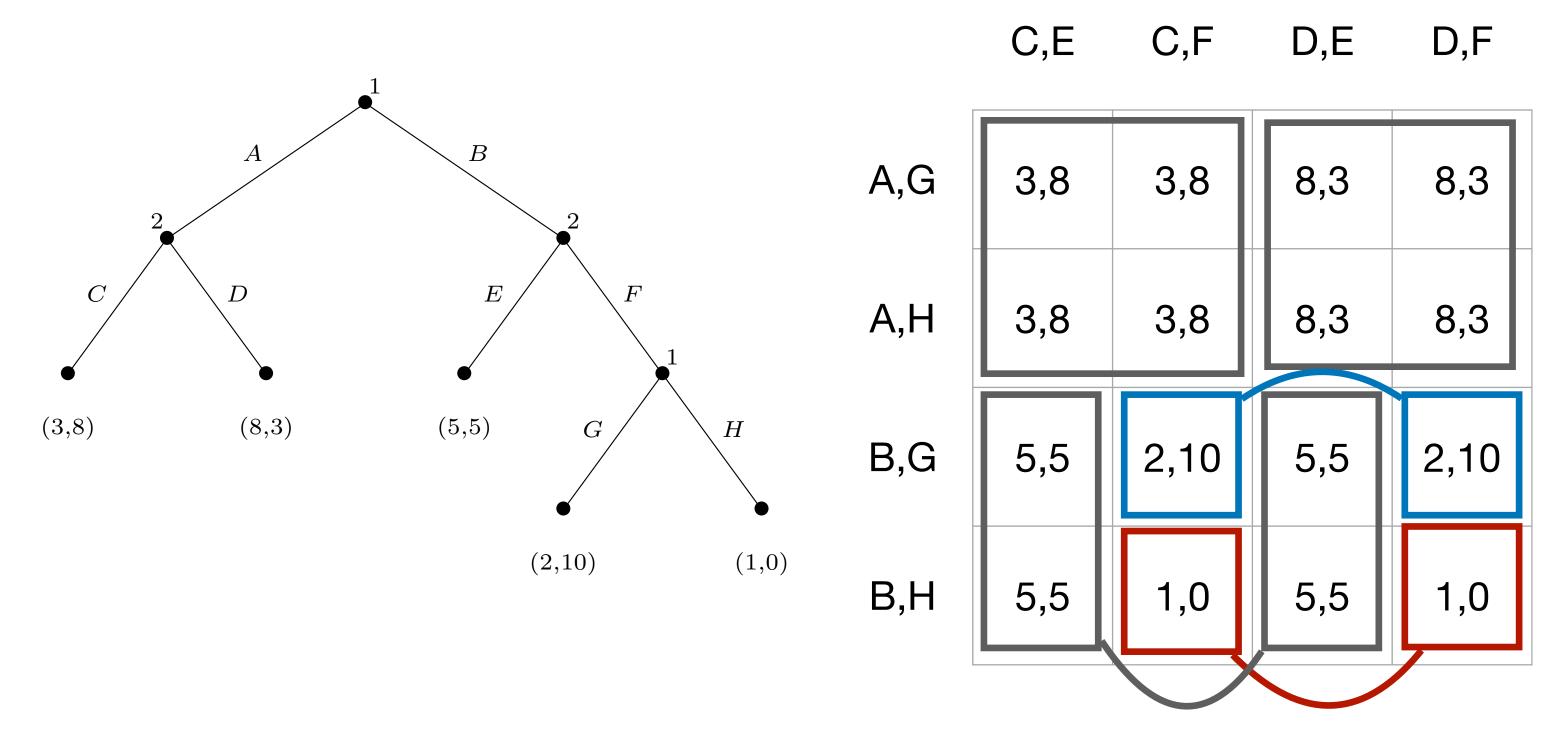

### **Definition:**

Let  $G = (N, A, H, Z, \chi, \rho, \sigma, u)$  be a perfect information game in extensive form. Then the **pure strategies of player** i consist of the cross product of actions available to player i at each of their choice nodes, i.e.,

$$\prod_{h \in H \mid \rho(h) = i} \chi(h).$$

Note: A pure strategy associates an action with **each** choice node, even those that will **never be reached**.

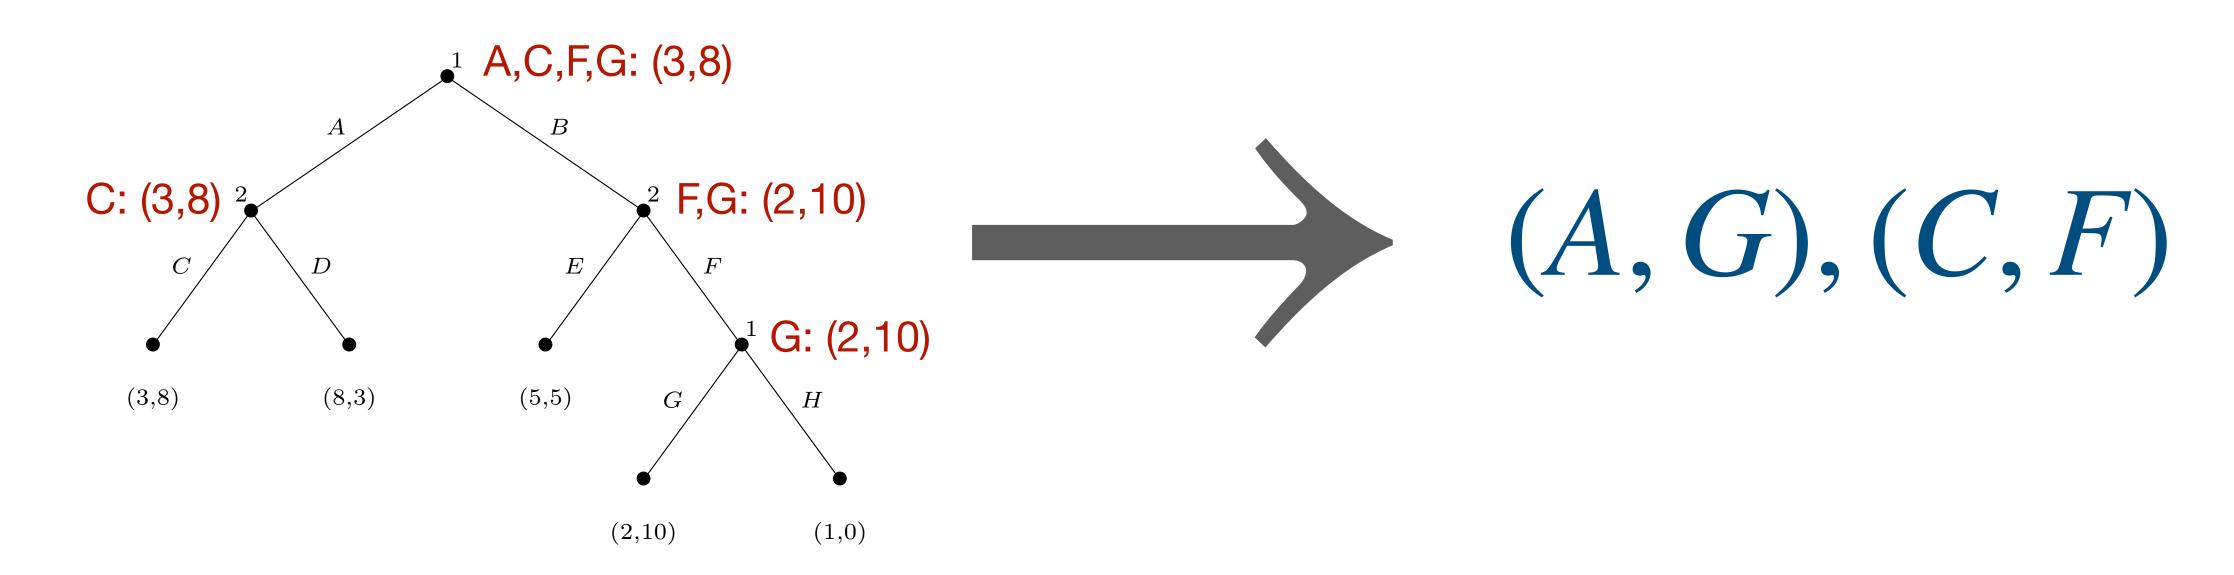

## Recap: Induced Normal Form

- Any pair of pure strategies uniquely identifies a terminal node, which identifies a utility for each agent
- We have now defined a set of agents, pure strategies, and utility functions
- Any extensive form game defines a corresponding induced normal form game

## Recap: Backward Induction

- Backward induction is a straightforward algorithm that is guaranteed to compute a subgame perfect equilibrium.
- Idea: Replace subgames lower in the tree with their equilibrium values

## Lecture Outline

- 1. Hints & Recap
- 2. Imperfect Information Games
- 3. Behavioural vs. Mixed Strategies
- 4. Perfect vs. Imperfect Recall
- 5. Computational Issues

## Imperfect Information, informally

- Perfect information games model sequential actions that are observed by all players
  - Randomness can be modelled by a special *Nature* player with constant utility
- But many games involve hidden actions
  - Cribbage, poker, Scrabble
  - Sometimes actions of the **players** are hidden, sometimes **Nature's** actions are hidden, sometimes both
- Imperfect information extensive form games are a model of games with sequential actions, some of which may be hidden

# Imperfect Information Extensive Form Game

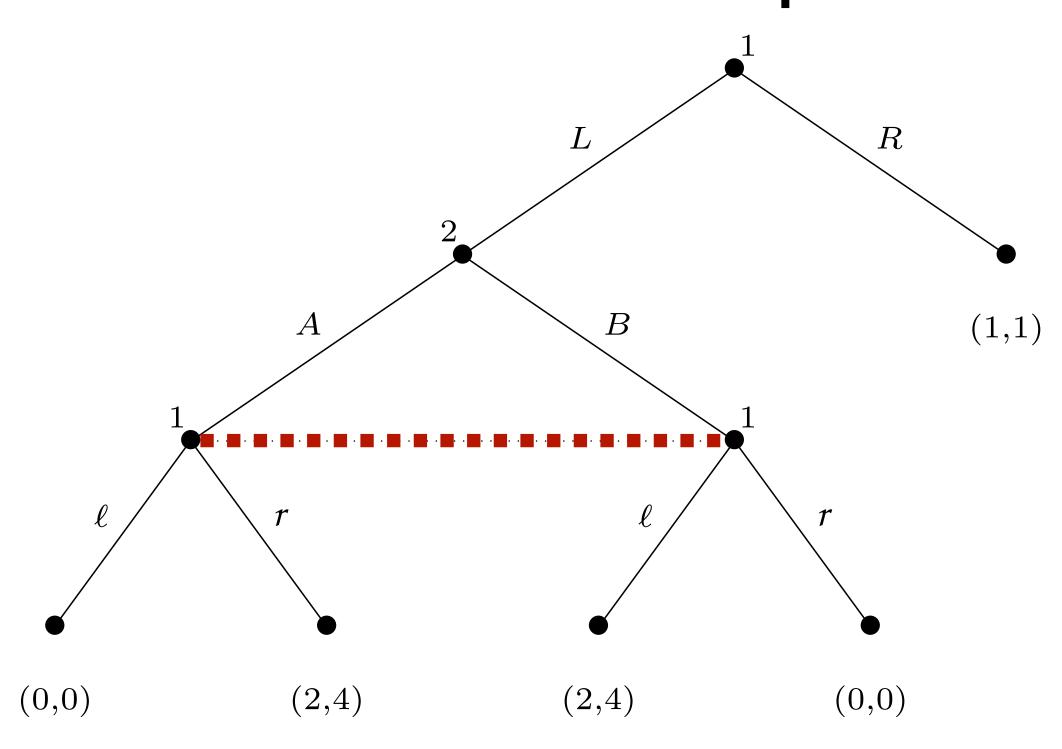

### **Definition:**

An imperfect information game in extensive form is a tuple

$$G = (N, A, H, Z, \chi, \rho, \sigma, u, I)$$
, where

- $(N, A, H, Z, \chi, \rho, \sigma, u)$  is a perfect information extensive form game, and
- $I=(I_1,\ldots,I_n)$ , where  $I_i=(I_{i,1},\ldots,I_{i,k_i})$  is an **equivalence relation** on (i.e., partition of)  $\{h\in H: \rho(h)=i\}$  with the property that  $\chi(h)=\chi(h')$  and  $\rho(h)=\rho(h')$  whenever there exists a j for which  $h\in I_{i,j}$  and  $h'\in I_{i,j}$ .

# Imperfect Information Extensive Form Example

- The elements of the partition are sometimes called information sets
- Players cannot distinguish which history they are in within an information set
- Question: What are the information sets for each player in this game?

# Pure Strategies

Question: What are the pure strategies in an imperfect information extensive form game?

### **Definition:**

Let  $G = (N, A, H, Z, \chi, \rho, \sigma, u, I)$  be an imperfect information game in extensive form. Then the **pure strategies of player i** consist of the cross product of actions available to player *i* at each of their **information sets**, i.e.,

$$\prod_{I_{i,j}\in I_i}\chi(I_{i,j}),$$

where for all  $I_{i,j} \in I_i$ ,  $\chi(I_{i,j}) \doteq \chi(h)$  for arbitrary  $h \in I_{i,j}$ .

 A pure strategy associates an action with each information set, even those that will never be reached

#### **Questions:**

In an imperfect information game:

- 1. What are the mixed strategies?
- 2. What is a best response?
- 3. What is a **Nash equilibrium**?

## Induced Normal Form

	Α	В
L,ℓ	0,0	2,4
L,r	2,4	0,0
R,ℓ	1,1	1,1
R,r	1,1	1,1

#### **Question:**

Can you represent an arbitrary perfect information extensive form game as an imperfect information extensive form game?

- Any pair of pure strategies uniquely identifies a terminal node, which identifies a utility for each agent
- We have now defined a set of agents, pure strategies, and utility functions
- Any extensive form game defines a corresponding induced normal form game

## Normal to Extensive Form

- Unlike perfect information games, we can go in the opposite direction and represent any normal form game as an imperfect information extensive form game
- Players can play in any order (why?)
- Question: What happens if we run this translation on the induced normal form?

# Behavioural vs. Mixed Strategies

### **Definition:**

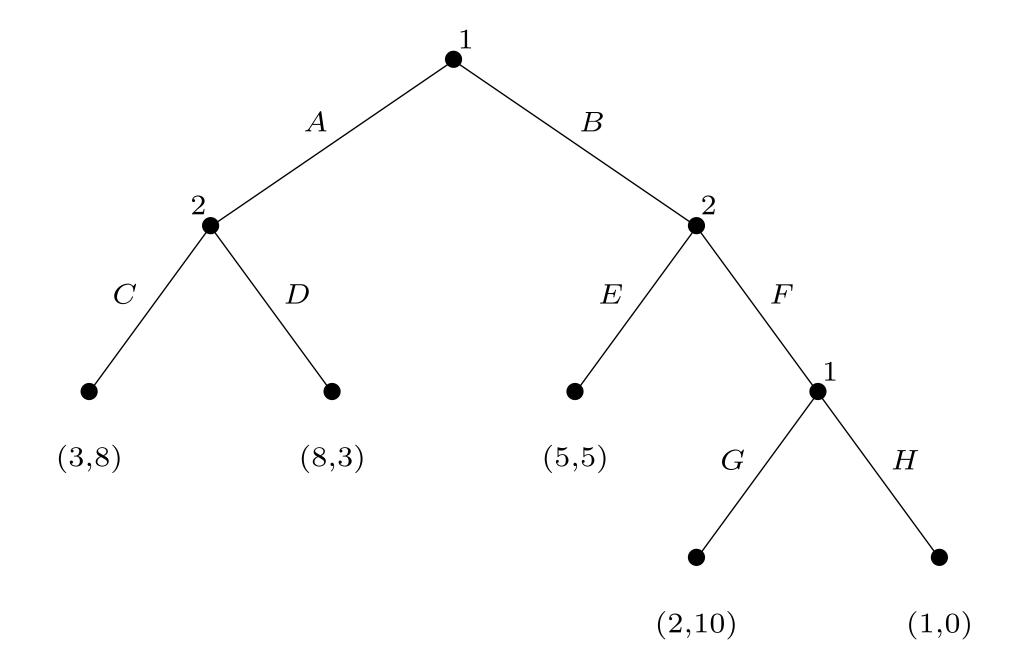

A mixed strategy  $s_i \in \Delta(A^{I_i})$  is any distribution over an agent's pure strategies.

### **Definition:**

A behavioural strategy  $b_i \in [\Delta(A)]^{l_i}$  is a probability distribution over an agent's actions at an information set, which is sampled independently each time the agent arrives at the information set.

# Behavioural vs. Mixed Example

- Behavioural strategy: ([.6:A, .4:B], [.6:G, .4:H])
- Mixed strategy: [.6:(A,G), .4:(B,H)]
- Question: Are these strategies equivalent?
   (why?)
- Question: Can you construct a mixed strategy that is equivalent to the behavioural strategy above?
- Question: Can you construct a behavioural strategy that is equivalent to the mixed strategy above?

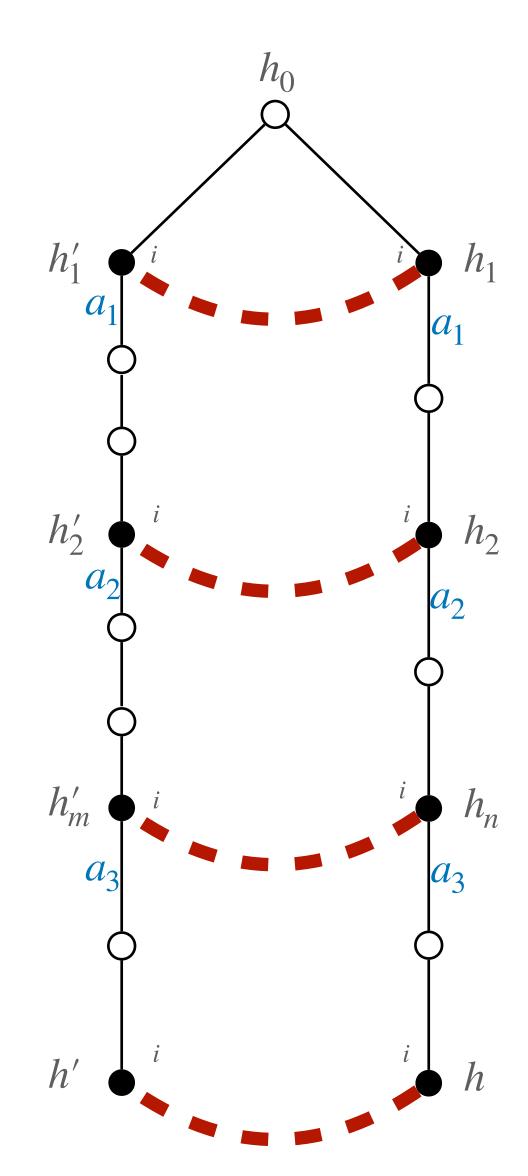

## Perfect Recall

#### **Definition:**

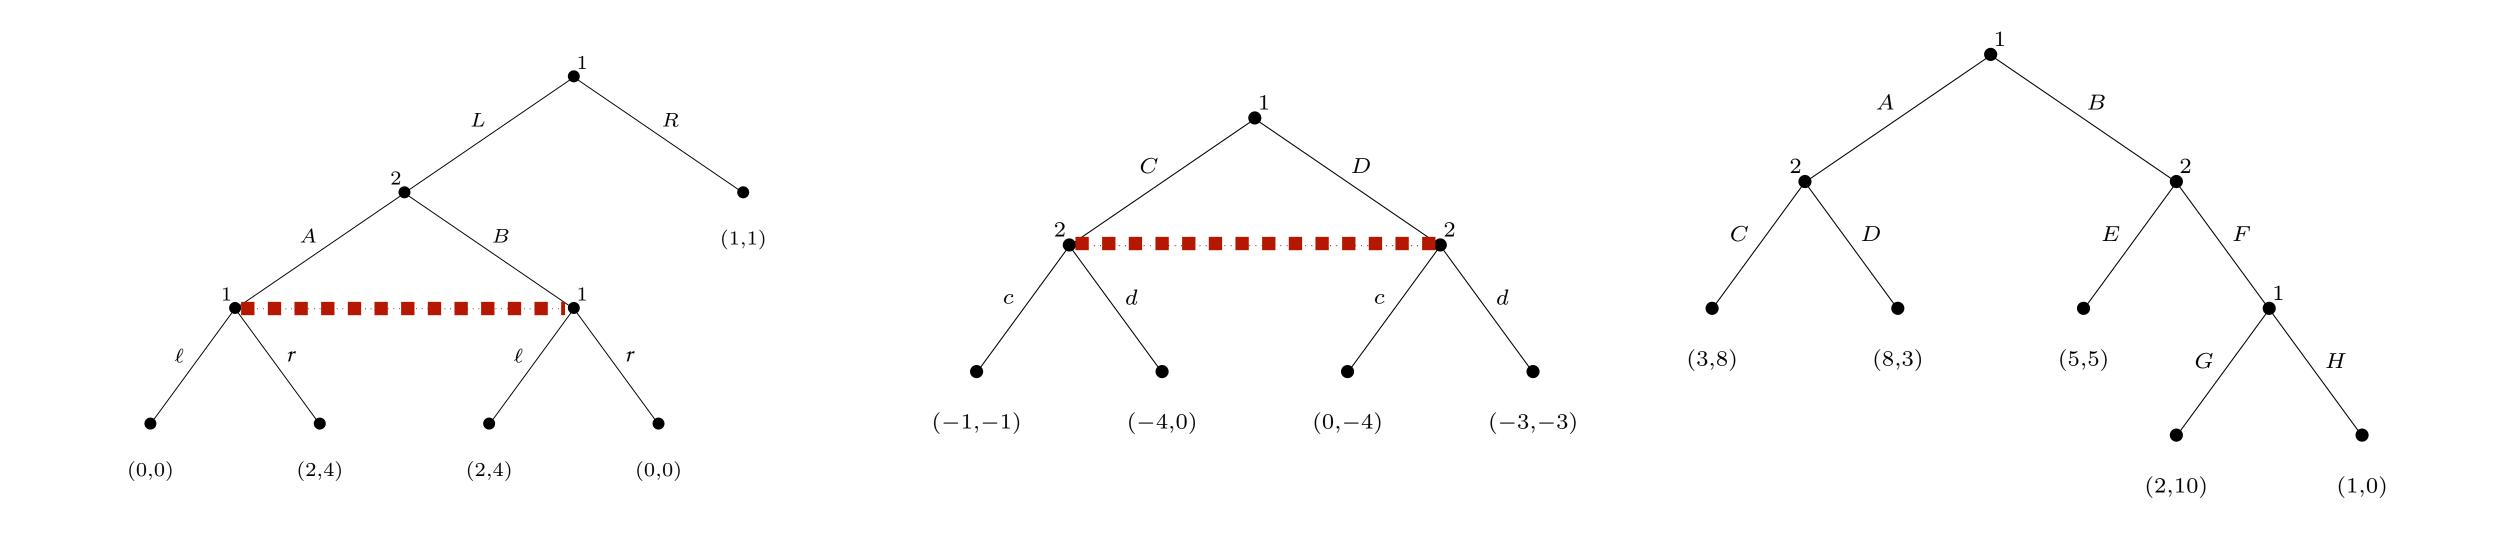

Player i has **perfect recall** in an imperfect information game G if for any two nodes h, h' that are in the same information set for player i, for any path  $h_0, a_0, h_1, a_1, \ldots, h_n, h$  from the root of the game to h, and for any path  $h_0, a'_0, h'_1, a'_1, \ldots, h'_m, h'$  from the root of the game to h', it must be the case that:

- 1. n = m, and
- 2. for all  $0 \le j \le n$ , if  $\rho(h_j) = i$ , then  $h_j$  and  $h'_j$  are in the same information set, and
- 3. for all  $0 \le j \le n$ , if  $\rho(h_j) = i$ , then  $a_j = a_j'$ .

G is a game of perfect recall if every player has perfect recall in G.

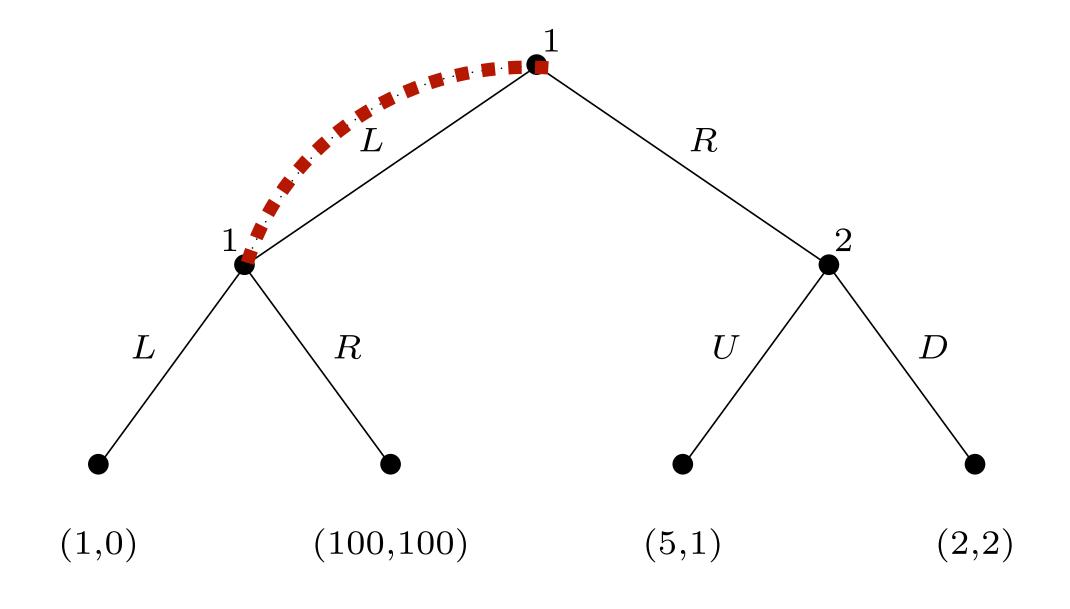

# Perfect Recall Examples

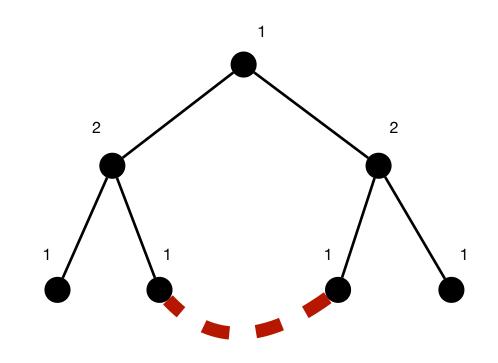

Question: Which of the above games is a game of perfect recall?

# Imperfect Recall Example

- Player 1 doesn't remember whether they have played *L* before or not. In this case, that is because they visit the **same information set multiple times**.
- Question: Can you construct a mixed strategy equivalent to the behavioural strategy [.5:L, .5R]?
- Question: Can you construct a behavioural strategy equivalent to the mixed strategy [.5:L, .5:R]?
- Question: What is the mixed strategy equilibrium in this game?
- Question: What is an equilibrium in behavioural strategies in this game?

# Imperfect Recall Applications

Question: When is it useful to model a scenario as a game of imperfect recall?

- 1. When the actual agents being modelled may forget previous history
  - Including cases where the agents strategies really are executed by proxies
- 2. As an approximation technique
  - E.g., poker: The exact cards that have been played to this point may not matter as much as some coarse grouping of which cards have been played
  - Grouping the cards into equivalence classes is a lossy approximation

## Kuhn's Theorem

Theorem: [Kuhn, 1953]

In a game of perfect recall, any **mixed strategy** of a given agent can be **replaced by an equivalent behavioural strategy**, and any **behavioural strategy** can be **replaced by an equivalent mixed strategy**.

 Here, two strategies are equivalent when they induce the same probabilities on outcomes, for any fixed strategy profile (mixed or behavioural) of the other agents.

## **Corollary:**

Restricting attention to behavioural strategies does not change the set of Nash equilibria in a game of perfect recall. (**why**?)

# Computing Nash Equilibria

- Question: Can we use backward induction to find an equilibrium in an imperfect information extensive form game?
- We can just use the induced normal form to find the equilibrium of any imperfect information game
  - But the induced normal form is exponentially larger than the extensive form
- Can use the sequence form [S&LB §5.2.3] in games of perfect recall:
  - **Zero-sum games: polynomial** in size of extensive form (i.e., exponentially faster than LP formulation on normal form)
  - General-sum games: exponential in size of extensive form (i.e., exponentially faster than converting to normal form)

# Summary

- Imperfect information extensive form games are a model of games with sequential actions, some of which may be hidden
  - Histories are partitioned into information sets
  - Player cannot distinguish between histories in the same information set
- Pure strategies map each information set to an action
  - Mixed strategies are distributions over pure strategies
  - Behavioural strategies map each information set to a distribution over actions
  - In games of perfect recall, mixed strategies and behavioural strategies are interchangeable
- A player has perfect recall if they never forget anything they knew about actions so far
