Inference in Belief Networks

CMPUT 366: Intelligent Systems

P&M §8.4

Assignment #1

- Assignment #1 is due Friday (Feb 4) at 11:59pm
- Submit via eclass: zipfile containing:
 - All code (yours and provided utility code)
 - PDF of problem set solutions

Lecture Outline

- 1. Recap
- 2. Factors
- 3. Variable Elimination
- 4. Efficiency

Recap: Belief Networks

Definition:

A belief network (or Bayesian network) consists of:

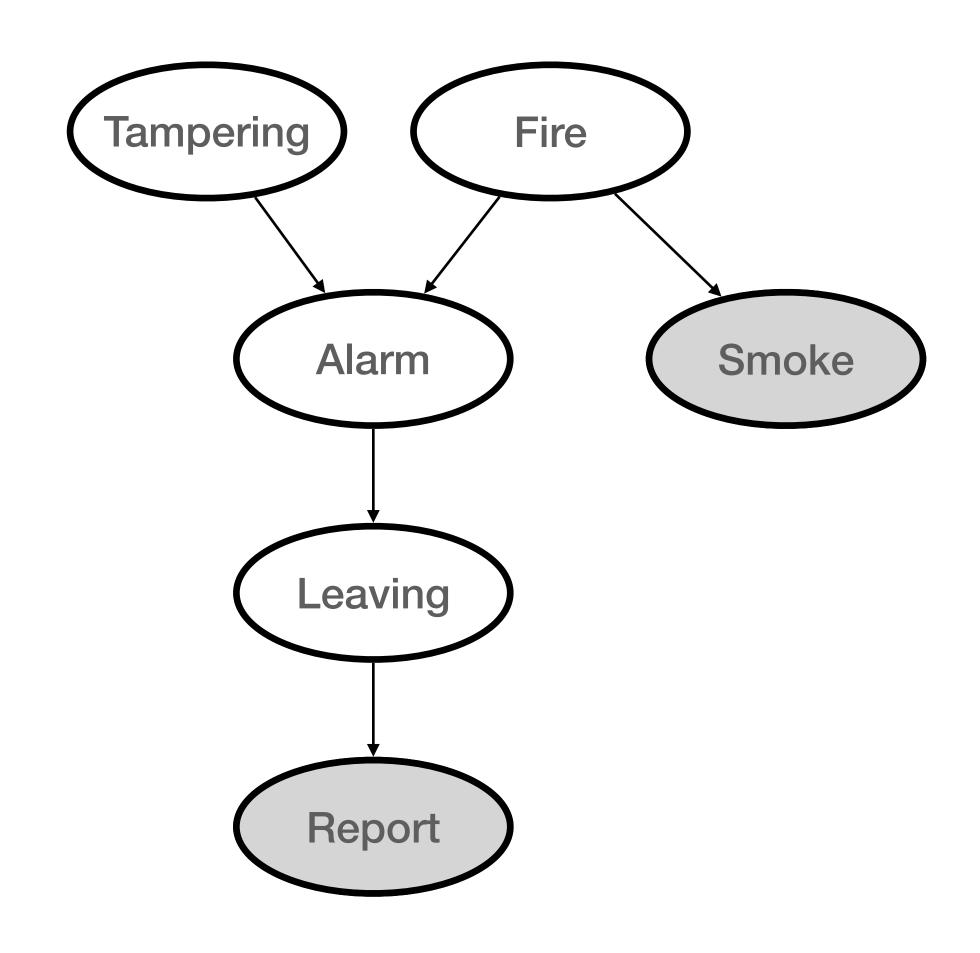

- 1. A directed acyclic graph, with each node labelled by a random variable
- 2. A domain for each random variable
- 3. A conditional probability table for each variable given its parents
- The graph represents a specific factorization of the full joint distribution

Semantics:

Every node is independent of its non-descendants, conditional on its parents

Recap: Queries

- The most common task for a belief network is to query posterior probabilities given some observations
- Easy cases:
 - Posteriors of a single variable conditional only on parents
 - Joint distributions of variables early in a compatible variable ordering
- Typically, the observations have no straightforward relationship to the target
- This lecture: mechanical procedure for computing arbitrary queries

Factors

- The Variable Elimination algorithm exploits the factorization of a joint probability distribution encoded by a belief network in order to answer queries
- A factor is a function $f(X_1, \ldots, X_k)$ from random variables to a real number
- Input: factors representing the conditional probability tables from the belief network
- $P(Leaving \mid Alarm)P(Smoke \mid Fire)P(Alarm \mid Tampering, Fire)P(Tampering)P(Fire)$ becomes

 $f_1(Leaving, Alarm)f_2(Smoke, Fire)f_3(Alarm, Tampering, Fire)f_4(Tampering)f_5(Fire)$

Output: A new factor encoding the target posterior distribution

E.g., $f_{12}(Tampering)$.

Conditional Probabilities as Factors

• A conditional probability $P(Y \mid X_1, \dots, X_n)$ is a factor $f(Y, X_1, \dots, X_n)$ that obeys the constraint:

$$\forall v_1 \in dom(X_1), v_2 \in dom(X_2), \dots, v_n \in dom(X_n) : \left[\sum_{y \in dom(Y)} f(y, v_1, \dots, v_n) \right] = 1.$$

- Answer to a query is a factor constructed by applying operations to the input factors
 - Operations on factors are not guaranteed to maintain this constraint!
 - Solution: Don't sweat it!
 - Operate on unnormalized probabilities during the computation
 - Normalize at the end of the algorithm to re-impose the constraint

Conditioning

Conditioning is an operation on a single factor

 Constructs a new factor that returns the values of the original factor with some of its inputs fixed

Definition:

For a factor $f_1(X_1, \ldots, X_k)$, conditioning on $X_i = v_i$ yields a new factor

$$f_2(X_1, ... X_{i-1}, X_{i+1}, ..., X_k) = (f_1)_{X_i = v_i}$$

such that for all values $v_1, ..., v_{i-1}, v_{i+1}, ..., v_k$ in the domain of $X_1, ..., X_{i-1}, X_{i+1}, ..., X_k$

$$f_2(v_1, ..., v_{i-1}, v_{i+1}, ..., v_k) = f_1(v_1, ..., v_{i-1}, \mathbf{v_i}, v_{i+1}, ..., v_k).$$

Conditioning Example

$$f_2(A, B) = f_1(A, B, C)_{C=true}$$

 f_1

Α	В	С	value
F	F	F	0.1
F	F	Т	0.88
F	Т	F	0.12
F	T	Τ	0.45
Т	F	F	0.7
Т	F	Т	0.66
Т	Т	F	0.1
Т	Т	Т	0.25

 f_2

Α	В	value
F	F	88.0
F	Τ	0.45
Т	F	0.66
Т	T	0.25

Multiplication

Multiplication is an operation on two factors

 Constructs a new factor that returns the product of the rows selected from each factor by its arguments

Definition:

For two factors $f_1(X_1, ..., X_j, Y_1, ..., Y_k)$ and $f_2(Y_1, ..., Y_k, Z_1, ..., Z_\ell)$,

multiplication of f_1 and f_2 yields a new factor

$$(f_1 \times f_2) = f_3(X_1, ..., X_j, Y_1, ..., Y_k, Z_1, ..., Z_\ell)$$

such that for all values $x_1, \ldots, x_j, y_1, \ldots, y_k, z_1, \ldots, z_\ell$,

$$f_3(x_1, ..., x_j, y_1, ..., y_k, z_1, ..., z_\ell) = f_1(x_1, ..., x_j, y_1, ..., y_k) f_2(y_1, ..., y_k, z_1, ..., z_\ell).$$

Multiplication Example

$$f_3(A, B, C) = f_1(A, B) \times f_2(B, C)$$

	f_1		_
A	В	value	
F	F	0.1	
F	Τ	0.2	
Т	F	0.3	Г
Τ	Τ	0.4	

	J_2		_
В	С	value	
F	F	1.0	
F	Τ	0	
T	F	0.5	
Т	Т	0.25	

_			3		_
	A	В	С	value	
	F	F	F	0.1	
	F	F	T	0	
	F	Τ	F	0.1	
	F	Т	Т	0.05	
	Т	F	F	0.3	
	Т	F	Т	0	
	Т	Т	F	0.2	
	Т	Т	Τ	0.1	

Summing Out

Summing out is an operation on a single factor

 Constructs a new factor that returns the sum over all values of a random variable of the original factor

Definition:

For a factor $f_1(X_1, ..., X_k)$, summing out a variable X_i yields a new factor

$$f_2(X_1, ..., X_{i-1}, X_{i+1}, ..., X_k) = \left(\sum_{X_i} f_1\right)$$

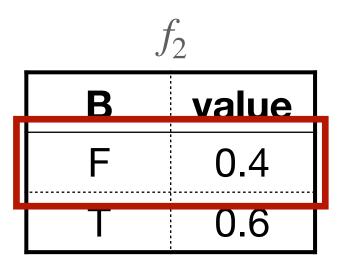

such that for all values $v_1, ..., v_{i-1}, v_{i+1}, ..., v_k$ in the domain of $X_1, ..., X_{i-1}, X_{i+1}, ..., X_k$

$$f_2(v_1, ..., v_{i-1}, v_{i+1}, ..., v_k) = \sum_{\mathbf{v_i} \in dom(X_i)} f_1(v_1, ..., v_{i-1}, \mathbf{v_i}, v_{i+1}, ..., v_k).$$

Summing Out Example

$$f_2(B) = \sum_A f_1(A, B)$$

	f_1		_
Α	В	value	
F	F	0.1	
F	Τ	0.2	Ц
Т	F	0.3	
Т	Т	0.4	

Variable Elimination

• Given observations $Y_1=v_1,\ldots,Y_k=v_k$ and query variable Q, we want

$$P(Q \mid Y_1 = v_1, ..., Y_k = v_k) = \frac{P(Q, Y_1 = v_1, ..., Y_k = v_k)}{\sum_{q \in dom(Q)} P(Q = q, Y_1 = v_1, ..., Y_k = v_k)}.$$

- Basic idea of variable elimination:
 - 1. Condition on observations by conditioning
 - 2. Construct joint distribution factor by multiplication
 - 3. Remove unwanted variables (neither query nor observed) by summing out
 - 4. Normalize at the end
- Doing these steps in order is correct but not efficient
- Efficiency comes from interleaving the order of operations

Sums of Products

- 2. Construct joint distribution factor by multiplication
- 3. Remove unwanted variables (neither query nor observed) by summing out

The computationally intensive part of variable elimination is computing sums of products

Example: multiply factors $f_1(Q, A, B, C)$, $f_2(C, D, E)$; sum out A, E

1.
$$f_3(Q, A, B, C, D, E) = f_1(Q, A, B, C) \times f_2(C, D, E) : 2^6$$
 multiplications

2.
$$f_4(Q, B, C, D) = \sum_{A,E} f_3(Q, A, B, C, D, E)$$
: 3 × 16 additions

Total: 112 computations

Efficient Sums of Products

We can reduce the number of computations required by changing their order.

$$\sum_{A} \sum_{E} f_1(Q, A, B, C) \times f_2(C, D, E)$$

$$= \left(\sum_{A} f_1(Q, A, B, C)\right) \times \left(\sum_{E} f_2(C, D, E)\right)$$

- 1. $f_3(C,D) = \sum_E f_2(C,D,E)$: 2^2 additions
- 2. $f_4(Q, B, C) = \Sigma_A f_1(Q, A, B, C)$: 2^3 additions
- 3. $f_5(Q, B, C, D) = f_3(Q, B, C) \times f_4(B, C, D) : 2^4$ multiplications

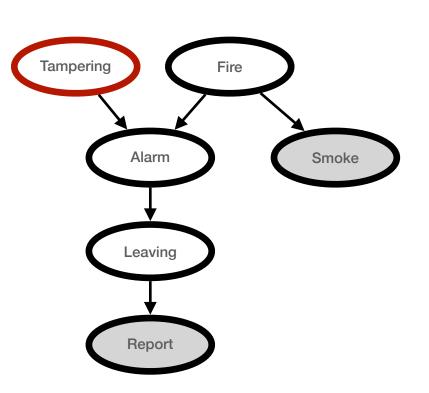

Total: 28 computations

Variable Elimination Algorithm

Input: query variable Q; set of variables Vs; observations O; factors Ps representing conditional probability tables

```
Fs := Ps
for each X in Vs \setminus \{Q\} according to some elimination ordering:
  Rs := \{ F \in Fs \mid F \text{ involves } X \}
   if X \in O:
     for each F \in Rs:
         F' := F conditioned on observed value of X
        Fs := (Fs \setminus \{F\}) \cup \{F'\}
   else:
      T := product of factors in Rs
     N := \mathbf{sum} X out of T
     Fs := (Fs \backslash Rs) \cup \{N\}
T := \mathbf{product} of factors in Fs
N := \mathbf{sum} \ Q out of T
return T/N (i.e., normalize T)
```

Variable Elimination Example: Conditioning

Query: P(Tampering | Smoke=true, Report=true)

Variable ordering: Smoke, Report, Fire, Alarm, Leaving

P(Tampering, Fire, Alarm, Smoke, Leaving, Report) = P(Tampering)P(Fire)P(Alarm|Tampering,Fire)P(Smoke|Fire)P(Leaving|Alarm)P(Report|Leaving)

Construct **factors** for each table:

{ f_0 (Tampering), f_1 (Fire), f_2 (Tampering, Alarm, Fire), f_3 (Smoke, Fire), f_4 (Leaving, Alarm), f_5 (Report, Leaving) }

Condition on Smoke: $f_6 = (f_3)_{\text{Smoke=true}}$

{ f_0 (Tampering), f_1 (Fire), f_2 (Tampering, Alarm, Fire), f_6 (Fire), f_4 (Leaving, Alarm), f_5 (Report, Leaving) }

Condition on Report: $f_7 = (f_5)_{Report=true}$

{ f_0 (Tampering), f_1 (Fire), f_2 (Tampering, Alarm, Fire), f_6 (Fire), f_4 (Leaving, Alarm), f_7 (Leaving) }

Variable Elimination Example: Elimination

```
Tampering Fire

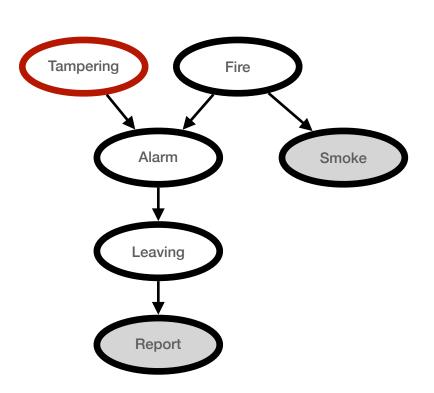

Alarm Smoke

Leaving

Report
```

```
Query: P(Tampering | Smoke=true, Report=true)
Variable ordering: Smoke, Report, Fire, Alarm, Leaving
{ f_0(Tampering), f_1(Fire), f_2(Tampering, Alarm, Fire), f_6(Fire), f_4(Leaving, Alarm), f_7(Leaving) }
Sum out Fire from product of f_1, f_2, f_6: f_8 = \sum_{\text{Fire}} (f_1 \times f_2 \times f_6)
{ f_0(Tampering), f_8(Tampering,Alarm), f_4(Leaving,Alarm), f_7(Leaving) }
Sum out Alarm from product of f_8, f_4: f_9 = \sum_{Alarm} (f_8 \times f_4)
{ f_0(Tampering), f_9(Tampering, Leaving), f_7(Leaving) }
Sum out Leaving from product of f_9, f_7: f_{10} = \sum_{\text{Leaving}} (f_9 \times f_7)
{ f_0(Tampering), f_{10}(Tampering) }
```

Variable Elimination Example: Normalization

```
Query: P(Tampering | Smoke=true, Report=true)
Variable ordering: Smoke, Report, Fire, Alarm, Leaving { f_0(Tampering), f_{10}(Tampering) }

Product of remaining factors: f_{11} = f_0 \times f_{10} { f_{11}(Tampering) }
```

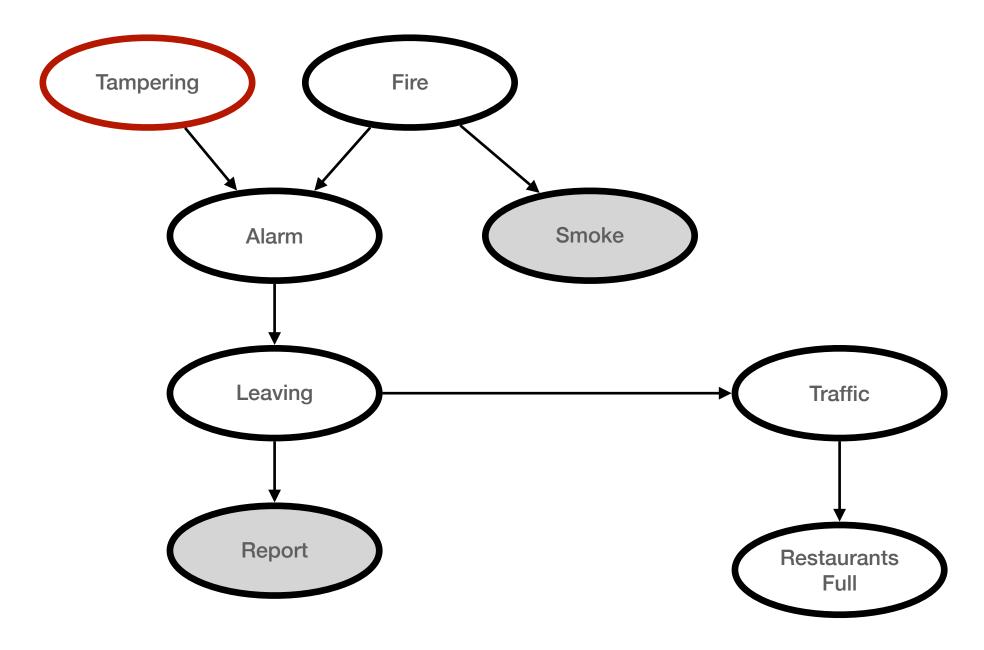

Normalize by division: query(Tampering) = f_{11} (Tampering) / ($\sum_{\text{Tampering}} f_{11}$ (Tampering))

Optimizing Elimination Order

- Variable elimination exploits efficient sums of products on a factored joint distribution
- The elimination order of the variables affects the efficiency of the algorithm
- Finding an optimal elimination ordering is NP-hard
- Heuristics (rules of thumb) for good orderings:
 - Observations first: Condition on all of the observed variables first
 - Min-factor: At every stage, select the variable that constructs the smallest new factor
 - Problem-specific heuristics

Optimization: Pruning

- The structure of the graph can allow us to drop leaf nodes that are neither observed nor queried
 - Summing them out for free
- We can repeat this process:

Optimization: Preprocessing

Finally, if we know that we are always going to be observing and/or querying the same variables, we can **preprocess** our graph; e.g.:

- 1. Precompute the **joint distribution** of all the variables we will observe and/or query
- 2. Precompute conditional distributions for our exact queries

Summary

- Variable elimination is an algorithm for answering queries based on a belief network
- Operates by using three operations on factors to reduce graph to a single posterior distribution
 - 1. Conditioning
 - 2. Multiplication
 - 3. Summing out
- Distributes operations more efficiently than taking full product and then summing out
 - Optimal order of operations is NP-hard to compute
- Additional optimization techniques: heuristic ordering, pruning, precomputation
