### Heuristic Search

CMPUT 261: Introduction to Artificial Intelligence

P&M §3.6

### Logistics

- Labs begin this week
  - Including a quick Python refresher
- Assignment #1 released later today
  - Download from (and submit on) eClass
  - Due: Thursday, September 28 at 11:59pm

### Lecture Outline

- 1. Logistics & Recap
- 2. Heuristics
- 3. A\* Search

#### After this lecture, you should be able to:

- Implement and demonstrate the operation of A\* search on a graph
- Identify whether a heuristic is admissible
- Construct an admissible heuristic for an arbitrary search problem
- Identify whether one heuristic dominates another
- Construct a dominating heuristic for a set of given heuristics
- Explain when a heuristic will allow more efficient exploration

### Recap: Uninformed Search

Different search strategies have different properties and behaviour

- Depth first search is space-efficient but not always complete or time-efficient
- Breadth first search is complete and always finds the shortest path to a goal, but is not space-efficient
- Iterative deepening search can provide the benefits of both, at the expense of some time-efficiency
- All three strategies must potentially explore every path, and are not guaranteed to return an optimal solution
- Least cost first search is optimal (under some conditions), but still must potentially explore every path

### Recap: Iterative Deepening Search

Input: a graph; a set of start nodes; a goal function

```
for max\_depth from 1 to \infty:
    more_nodes := False
    frontier := \{\langle s \rangle \mid s \text{ is a start node}\}
   while frontier is not empty:
      select the newest path \langle n_0, ..., n_k \rangle from frontier
      remove \langle n_0, ..., n_k \rangle from frontier
      if goal(n_k):
          return \langle n_0, \ldots, n_k \rangle
      if k < max_depth:
          for each neighbour n of n_k:
             add \langle n_0, ..., n_k, n \rangle to frontier
      else if n_k has neighbours:
          more nodes := True
   end-while
   if more_nodes = False:
       return None
```

### Recap: Optimality

#### **Definition:**

An algorithm is **optimal** if it is guaranteed to return an optimal (i.e., **minimal-cost**) solution **first**.

- Depth-first search, breadth-first search, iterative deepening search are not optimal
- Least-cost first search is optimal (if there is a positive lower bound on arc costs)

# Recap: Search Strategies

	Depth First	Breadth First	Iterative Deepening	Least Cost First
Selection	Newest	Oldest	Newest, multiple	Cheapest
Data structure	Stack	Queue	Stack, counter	Priority queue
Complete?	Finite graphs only	Complete	Complete	Complete if $cost(p) > \varepsilon$
Space complexity	O(mb)	O(b <sup>m</sup> )	O(mb)	O(b <sup>m</sup> )
Time complexity	O(b <sup>m</sup> )	$O(b^m)$	O(mbm) **	O(b <sup>m</sup> )
Optimal?	No	No	No	Optimal

### Domain Knowledge

- Domain-specific knowledge can help speed up search by identifying promising directions to explore
- We will encode this knowledge in a function called a heuristic function which estimates the cost to get from a node to a goal node
- The search algorithms in this lecture take account of this heuristic knowledge when **selecting** a path from the frontier

### Heuristic Function

#### **Definition:**

A **heuristic function** is a function h(n) that returns a non-negative estimate of the cost of the **cheapest** path from node n to **some** goal node.

- For paths:  $h(\langle n_0, ..., n_k \rangle) = h(n_k)$
- Uses only **readily-available** information about a node (i.e., easy to compute)
- Problem-specific

### Admissible Heuristic

#### **Definition:**

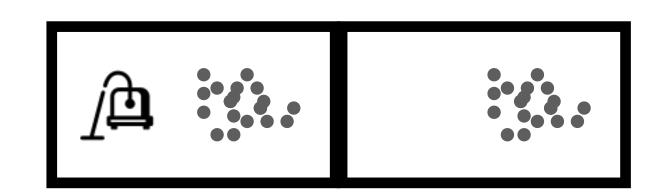

A heuristic function is admissible if h(n) is always less than or equal to the actual cost of the cheapest path from n to any goal node.

• i.e., h(n) is a lower bound on  $cost(\langle n, ..., g \rangle)$  for any goal node g

### Example Heuristics

 Number of dirty rooms for VacuumBot (ignores the need to move between rooms)

Euclidean distance for DeliveryBot

 Points for chess pieces (ignores positional strength)

Question: Which of these heuristics are admissible? Why?

# Constructing Admissible Heuristics

- Search problems try to find a cost-minimizing path, subject to constraints encoded in the search graph
- How to construct an easier problem? Drop some constraints.
  - This is called a relaxation of the original problem
- The cost of the optimal solution to the relaxation will always be an admissible heuristic for the original problem (Why?)
- Neat trick: If you have two admissible heuristics  $h_1$  and  $h_2$ , then  $h_3(n)=\max\{h_1(n),h_2(n)\}$  is admissible too! (Why?)

### Simple Uses of Heuristics

- Heuristic depth first search: Add neighbours to the frontier in decreasing order of their heuristic values, then run depth first search as usual
  - Will explore most promising successors first, but
  - Still explores all paths through a successor before considering other successors
  - Not complete, not optimal
- Greedy best first search: Select path from the frontier with the lowest heuristic value
  - Not guaranteed to work any better than breadth first search (why?)

### A\* Search

- A\* search uses **both** path cost information and heuristic information to select paths from the frontier
- Let f(p) = cost(p) + h(p)
  - f(p) estimates the total cost to the nearest goal node starting from p
- A\* removes paths from the frontier with smallest f(p)
- When h is admissible,  $p^* = \langle s, ..., n, ..., g \rangle$  is a solution, and  $p' = \langle s, ..., n \rangle$  is a prefix of  $p^*$ :

• 
$$f(p') \leq cost(p^*)$$
 (why?)

$$\underbrace{\frac{\text{actual}}{\text{cost(p)}} n} \underbrace{\frac{\text{estimated}}{\text{b(n)}}}_{\text{goal}}$$

# A\* Search Algorithm

**Input:** a *graph*; a set of *start nodes*; a *goal* function

```
frontier := \{\langle s \rangle \mid s \text{ is a start node}\}
while frontier is not empty:
    select f-minimizing path \langle n_0, ..., n_k \rangle from frontier
    remove \langle n_0, ..., n_k \rangle from frontier
    if goal(n_k):
       return \langle n_0, \ldots, n_k \rangle
   for each neighbour n of n_k:
       add \langle n_0, ..., n_k, n \rangle to frontier
```

end while

#### i.e., $f(\langle n_0, ..., n_k \rangle) \leq f(p)$ for all other paths $p \in frontier$

#### **Question:**

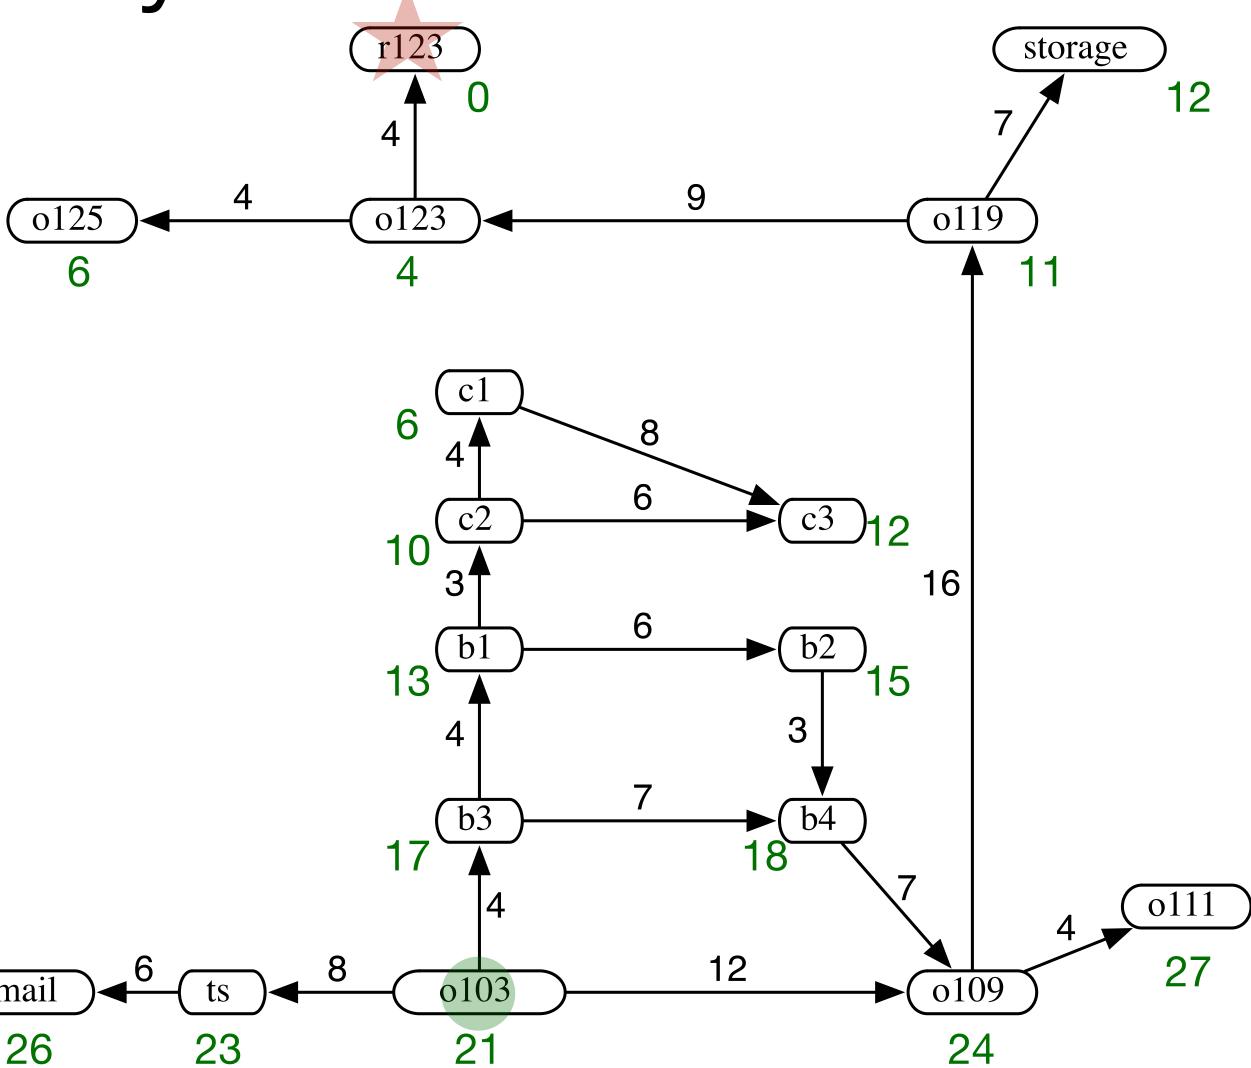

What data structure for the frontier implements this search strategy?

# A\* Search Example: DeliveryBot

• Heuristic: Euclidean distance

• Question: What is  $f(\langle o103,b3\rangle)$ ?  $f(\langle o103,o109\rangle)$ ?

- A\* will spend a bit of time exploring paths in the labs before trying to go around via o109
- At that point the heuristic starts helping more
- Question: Does breadth-first search explore paths in the lab too?
- Question: Does breadth-first search explore any paths that A\* does not?

# A\* Optimality

#### Theorem:

If there is a solution of finite cost,  $A^*$  using heuristic function h always returns an **optimal** solution (in **finite time**), if

- 1. The branching factor is finite, and
- 2. All arc costs are greater than some  $\epsilon > 0$ , and
- 3. h is an admissible heuristic.

#### **Proof:**

- No suboptimal solution will be removed from the frontier whenever the frontier contains a prefix of the optimal solution
- 2. The optimal solution is guaranteed to be removed from the frontier eventually

## A\* Optimality Proofs: A Lexicon

An admissible heuristic: h(n)

$$f(\langle n_0, ..., n_k \rangle) = \operatorname{cost}(\langle n_0, ..., n_k \rangle) + h(n_k)$$

A start node: S

A goal node: z (i.e., goal(z) = 1)

The optimal solution:  $p^* = \langle s, ..., a, b, ...z \rangle$ 

A prefix of the optimal solution:  $p' = \langle s, ..., a \rangle$ 

A suboptimal solution:  $g = \langle s, q, ..., z \rangle$ 

# A\* Optimality

**Proof part 1:** Optimality (no g is removed before  $p^*$ )

1. 
$$f(g) = cost(g)$$
 and  $f(p^*) = cost(p^*)$ 

(i) 
$$f(\langle n_0, ..., n_k \rangle) = \operatorname{cost}(\langle n_0, ..., n_k \rangle) + h(n_k)$$
, and  $h(z) = 0$ 

2. f(p') < f(g)

(i) 
$$f(\langle s, ..., a \rangle) = cost(\langle s, ..., a \rangle) + h(a)$$

(ii) 
$$f(\langle s, ..., a, b, ..., z \rangle) = cost(\langle s, ..., a, b, ..., z \rangle) + h(z) = cost(\langle s, ..., a \rangle) + cost(\langle s, ..., z \rangle)$$

(iii) 
$$h(a) \leq \cot(\langle a, b, ..., z \rangle)$$

(iv) 
$$f(p') \le f(p^*) < f(g)$$

An admissible heuristic: h(n)  $f(\langle n_0, ..., n_k \rangle) = \cot(\langle n_0, ..., n_k \rangle) + h(n_k)$ A start node: sA goal node: z (i.e.,  $\gcd(z) = 1$ )
The optimal solution:  $p^* = \langle s, ..., a, b, ...z \rangle$ A prefix of the optimal solution:  $p' = \langle s, ..., a \rangle$ A suboptimal solution:  $g = \langle s, q, ..., z \rangle$ 

## A\* Completeness

# An admissible heuristic: h(n) $f(\langle n_0, ..., n_k \rangle) = \operatorname{cost}(\langle n_0, ..., n_k \rangle) + h(n_k)$ A start node: sA goal node: z (i.e., $\operatorname{goal}(z) = 1$ ) The optimal solution: $p^* = \langle s, ..., a, b, ...z \rangle$

A **prefix** of the optimal solution:  $p' = \langle s, ..., a \rangle$ 

A suboptimal solution:  $g = \langle s, q, ..., z \rangle$ 

#### **Proof part 2:** A\* is complete

- Every path that is removed from the frontier is only replaced by more-costly paths (why?)
- Since individual arc costs are larger than  $\epsilon$ , every path in the frontier will eventually have cost larger than k, for any finite k
  - . Every path with at least  $\frac{k}{\epsilon}$  arcs will have cost larger than k
- So every path in the frontier will eventually have cost larger than the cost of the optimal solution
- So the optimal solution will eventually be removed from the frontier
- Question: Why are we talking about costs and not f-values?

### Comparing Heuristics

- Suppose that we have two admissible heuristics,  $h_1$  and  $h_2$
- Suppose that for every node n,  $h_2(n) \ge h_1(n)$

**Question:** Which heuristic is better for search (with A\*)?

## Dominating Heuristics

#### **Definition:**

A heuristic  $h_2$  dominates a heuristic  $h_1$  if

- 1.  $\forall n : h_2(n) \ge h_1(n)$ , and
- 2.  $\exists n : h_2(n) > h_1(n)$ .

#### Theorem:

If  $h_2$  dominates  $h_1$ , and both heuristics are admissible, then A\* using  $h_2$  will never remove more paths from the frontier than A\* using  $h_1$ .

• i.e., better heuristics remove weakly fewer paths

#### **Question:**

Which admissible heuristic dominates all other admissible heuristics?

### A\* Analysis

For a search graph with *finite* maximum branch factor b and *finite* maximum path length m...

- 1. What is the worst-case space complexity of A\*? [A: O(m)] [B: O(mb)] [C:  $O(b^m)$ ] [D: it depends]
- 2. What is the worst-case time complexity of A\*? [A: O(m)] [B: O(mb)] [C:  $O(b^m)$ ] [D: it depends]

**Question:** If A\* has the same space and time complexity as least cost first search, then what is its advantage?

### Summary

- Domain knowledge can help speed up graph search
- Domain knowledge can be expressed by a heuristic function, which estimates the cost of a path to the goal from a node
- Admissible heuristics can be built from relaxations of the original problem
- Simple uses of heuristics do not guarantee improved performance
- A\* algorithm for use of admissible heuristics with guarantees
